

WEB BASED DYNAMIC DATA TRANSLATION SERVICE AND METHOD

ABSTRACT OF THE DISCLOSURE

A method and system of translating data from a first format into one or more translated formats includes initiating a translation request on one of plurality of client systems. The translation request includes source data to be translated from the first format into desired translated formats and configuration data defining each type of translation to be performed on the source data. The translation request is communicated to a server system and is processed on the server system to determine from the configuration data the type of each data translation to be performed on the data. The data is provided to an appropriate translation service on the server system and is translated to the appropriate translated format via the corresponding translation service. A return translation request is communicated to the client system, the return translation request including the data in each translated format.
